Abstract
Various parameters are taken into account when calculating fleet in maritime transport. The most important of these is fuel consumption. Since the fuel consumption is proportional to the speed of the ship, high speed brings high fuel consumption. Increasing number of ship means increasing costs. In this study, we use the greatest integer function to find the optimum number of ship with lower cost. In addition, we calculate daily freight for voyage charterer depending on the number of ships by using this function.

Keywords: Maritime Transportation, Number of Fleet, Fuel Consumption.

DOI: 10.7176/JSTR/5-9-02

1. Introduction
Experimental data show that fuel consumption varies geometrically with increasing speed. For example, at some speeds, when you increase your ship's speed by 30%, your consumption is twice as fast as the original speed. While the vessels are anchored in the port, roughly a quarter of the fuel consumption in the sea is produced by fuel fuels [1]. In the case of neglecting the load on it, there is a classical correlation which is proportional to the power to increase the speed and fuel consumption by showing the fuel consumption of a ship with F. That is,

\[ F(v) = \lambda \cdot v^\Omega \]

\[ \lambda > 0 \]

[2]

However, since there are some fixed costs to show with s, a daily cost of a ship is \( C_1 = s + F(v) \). Similarly, the 1-day cost of n homogenous ships is \( C_n = n(s + F(v)) = n \cdot C_1 \) [3]

As can be seen, the number of ships and the cost are increasing in direct proportion, but if the speed is inversely proportional to the strength of the speed, the cost can be further reduced by increasing the number of ships by only 1 and reducing the speed to a very small amount.

Example 1.1
For a ship with fixed cost \( s = $1000 \) and speed \( v = 20,1 \) knots, \( \lambda = 0.64 \) means that a 1(one) day cost is \( C_1 = $6197 \). For two smaller vessels with the same characteristics but with a speed \( v = 20 \) knots, the cost would be \( C_2 = $12240 \). At first glance it may seem more costly to ship 2 slower and smaller vessels, but the increase in the number of vessels will cause the cost to decrease. For example, for \( n = 10 \) vessels, \( C_{10} = $61970, C_{11} = $67320 \). For the convenience of calculation, \( \Omega = 3 \) is taken for convenience, and the fixed cost is considered unaffected by a very small reduction of 0.1 knots. In Table 1, ship number relationships are given for \( s = $1000 \) and \( \lambda = 0.64 \). [4]
As shown in the table above, the cost of 80 ships at 20.1 kt is greater than the speed of 81 ships at 20 kt. In other words, although we have increased the number of vessels, our costs have been reduced by only 0.1 kt slowdown.

2. The Greatest Integer Function

For all real numbers, \( x \), the greatest integer function returns the largest integer less than or equal to \( x \). In essence, it rounds down a real number to the nearest integer. It is denoted by \( \lfloor x \rfloor \).

\[ f : \mathbb{R} \rightarrow \mathbb{Z}, \quad f(x) = \lfloor x \rfloor. \]

The greatest integer function has these properties:

(i) \( k \in \mathbb{Z} \) such that \( f(x) = k \iff k \leq x < k + 1 \)

(ii) For all \( x \in \mathbb{R} \) and \( k \in \mathbb{Z} \), \( f(x+k) = f(x) + k \)

(iii) For all \( x \in \mathbb{R} \), if \( x \leq f(x) < x + 1 \)

**Proposition 2.1**

\( C'_1 \) and \( C_1 \) are the costs of two ships which are slow and fast respectively. Let \( \kappa \) be the greatest integer function and let \( n \) be the number of the ship. The smallest natural number \( n \) providing the inequality of \((n+1). C'_1 < n.C_1\) is \( \kappa (\frac{C'_1 - C_1}{C_1}) + 1 \) This equation does not depend on the changing of the fixed cost \( s \).

**Proof:**

We know that \( C'_1 = s' + F(v') \), \( C_1 = s + F(v) \)

Let \((n+1). C'_1 < n. C_1\) be obtained. Let \((n+1). C'_1 < n. C_1\)

\( C'_1 + C_1 < n. C_1 \)

\( C'_1 < n. (C_1 - C'_1) \)

\( \frac{C'_1}{C_1 - C'_1} < n \)

According to the third property of the greatest integer function, the smallest natural number \( n \) providing the inequality is \( n = \kappa (\frac{C'_1}{C_1 - C'_1}) + 1 \)

If we use this proposition, we can calculate the number of the ship in example 1.

\( n = \kappa (\frac{C'_1}{C_1 - C'_1}) + 1 = [\frac{120}{77}] + 1 = [17] + 1 = 18 \) so, \( C_{80} = 495774.77 \) and \( C_{81} = 495720 \). We showed that cost of 80 ships are greater than 81 ships in the table 1 before. So, we can calculate this by using Proposition 2.1.

In some cases it may be less costly to do a few times with smaller vessels. To generalize this situation, the optimal number of vessels can be found by the following proposition.

**Proposition 2.2**

Let \( C_1 \) and \( C'_1 \) functions be the consumption functions of the two large and small ships respectively. Let \( \kappa \) be the greatest integer function. For \( m>n \), the smallest natural number \( n \) providing the inequality \( n. C_1 > m.C'_1 \) is \( \kappa (\frac{C'_1}{C_1 - C'_1}) + 1 \).

**Proof:**

Let \( n.C_1 > m.C'_1 \) be obtained. for \( m>n \). and \( s' \) be the fixed cost of \( C'_1 \). So,

\( m.(s'+F(v')) < n.s + n.F(v) \)

\( \Rightarrow m.s + m.F(v') < n.s + n.F(v) \)

\( m>n \) obtains \( m=n+k, k \in \mathbb{Z} \)

\( n.s + n.F(v') + k.s + k.F(v') < n.s + n.F(v) \)

\( \Rightarrow k.s + k.F(v') < n.s + n.F(v) - n.s - n.F(v') \)
\[ \Rightarrow k.(s' + F(v')) < n.(s + F(v) - (s'|v')) \]
\[ \Rightarrow n > \frac{C_1'}{C_1 - C_1'} \]
\[ \Rightarrow n > \frac{C_1'}{C_1 - C_1'} \]

the smallest natural number \( n \) providing the equality is \( n = \kappa \left( \frac{C_1'}{C_1 - C_1'} \right) + 1 \)

3. Voyage Charter

Instead of increasing the number of ships, it will be more profitable to carry the maximum load in the shortest time by reducing the time of the voyage for voyage charter. In other word, we must increase the speed.

\[ 16\lambda P v^3 + \lambda D v^2 = 8F \] equation is valid for this transportation. Here \( D \), Number of days at sea; \( P \) stands for the number of days in port and \( F \) stands for freight earned. In particular, if we take \( P = 0 \), we get the equation \( kDv^2 = 8F \) [1]

Example 3.1

Let \( \lambda \) be the constant for the ship and \( v \) be the speed of the ship. If \( \lambda = 0.5 \) and \( v = 10 \text{kt} \), then earned freight is \( 8F = $50 \). But, if we increase the speed by 0.5 knots, earned freight will be \( 8F = $55; 125 \) [1]

Proposition 3.2

Let \( \kappa \) be the greatest integer function \( v_1 \) and \( v_2 \) are the speeds of the ship, \( D \) be the number of the day and \( v_1 < v_2 \). If we take \( D = \kappa \left( \frac{v_2^2}{v_2^2 - v_1^2} \right) \) then \( (D - 1)v_2^2 < D.v_1^2 \) inequality is obtained.

Proof:

If we consider \( (D - 1)v_2^2 < D.v_1^2 \) inequality, we can divide by \( D \) and we get \( D < \frac{v_2^2}{v_2^2 - v_1^2} \) The smallest \( D \) number that satisfies this condition is \( D = \kappa \left( \frac{v_2^2}{v_2^2 - v_1^2} \right) \).

Now we can use this proposition on example 2.

If we take \( D = \kappa \left( \frac{v_2^2}{v_2^2 - v_1^2} \right) = \kappa \left( \frac{110.25}{10.25} \right) = 10 \), we have \( 10 \times 0.5 \times 10^2 = 500 = 8F \) And for \( (D - 1) \) day, \( 9 \times 0.5 \times 10.5^2 = 496.125 = 8F \) that means spending longer days with lower speed is more profitable than spending shorter days with higher speed.

4. Literature Review.

5. Results

In the first part of the study a very small decrease in speed has been shown to have a positive effect on increasing the number of ships. We can calculate optimum number of the ship with “greatest integer function” which is represented by \( \kappa \) in this study. It has been shown that the smallest number of vessels providing \( n.C_2 > m.C_1 \), inequality for \( n > m \), which is the consumption functions of two large and small vessels, respectively, \( C_1 \) and \( C_1' \), is \( \kappa \left( \frac{C_1'}{C_1 - C_1'} \right) + 1 \) In this way, 20.81 ships departing at a cost of $ 495774.77 from 20.1 kt. The cost of 80 vessels traveling quickly was found to be $ 495720.

In the second part, it is seen that the same function can be applied for a voyage charter. In addition, we see that spending longer days with lower speed is more profitable than spending shorter days with higher speed for voyage charter.
